

ABSTRACT

In the shoulder belt to be hung from one shoulder to a waist opposite to the shoulder, tip portions of a pair of shoulder belt parts, which are located in front and back of a human body respectively, are connected through two
5 connecting belts which are overlapped each other such that longitudinal central portions are separated laterally. The two connecting belts constitute a shoulder locking belt portion to be hung on an upper surface of a shoulder and an upper arm locking belt portion to be hung on an outer surface of a upper arm in a vicinity of a shoulder joint, and are hung on the upper surface
10 of the shoulder and the outer surface of the upper arm, thereby distributing the load applied to the shoulder belt.
